

Radiation Exposure – Units of Measurement

The following units measure physical effects of radiation:

1. The becquerel (Bq) : This is the smallest unit used to measure the number of disintegrations per second undergone by a radioactive substance. $1 \text{ Bq} = 1 \text{ disintegration per second}$
2. The curie (Ci) : This is the largest unit used to measure the number of disintegrations per second undergone by a radioactive substance. $1 \text{ Ci} = 37 \text{ billion disintegrations per second}$ (NB. 1 g radium emits this amount of radiation)

NB. The above units give the # of disintegrations per second, but they don't tell the amount of E released.

The following units measure amount of E released:

1. The rad (rd) : This is the smallest unit used to measure the quantity of energy absorbed per kilogram of living tissue.
2. The gray (Gy) : This is the largest unit used to measure the quantity of energy absorbed per kilogram of living tissue. $1 \text{ Gy} = 100 \text{ rds}$

The following units measure the biological damage produced by radiation:

1. The rem : This is the smallest unit used to measure the biological damage resulting from a dose of ionizing radiation absorbed by living matter.
2. The sievert (Sv) : This is the largest unit used to measure the biological damage resulting from a dose of ionizing radiation absorbed by living matter. $1 \text{ Sv} = 100 \text{ rem}$
